

Session 7

What is Programming?

- A set of instructions written to a computer to perform a specific task.
- Computer Devices (Any device containing Central Processing Unit CPU) consist of tiny transistors (Switches)
- If the transistor is closed, it takes a value of 1
- If it is opened, it takes a value of 0

Types Of Programming languages

Low Level

101010
010101
101010
010101

Machine Language
(Binary)

Assembly Language

C language

High level

Modern Programming languages

Close to human language

A little Comparision

Let's Print the word (Hello)!

101010
010101
101010
010101

1001000 1100101 1101100
1101100 1101111

Assembly

```
; assemble and link with:  
; nasm -f elf test.asm && gcc -m32 -o test test.o  
section .text  
extern printf ; If you need other functions, list them in a similar way  
global main  
  
main:  
    mov eax, 0x21 ; The '!' character  
    push eax  
    push message  
    call printf  
    add esp, 8 ; Restore stack - 4 bytes for eax, and 4 bytes for 'message'  
    ret  
  
message db 'The character is: %c', 10, 0
```

```
#include <iostream>  
using namespace std;  
int main() {  
    cout << "Hello";  
    return 0;  
}
```

```
print ("Hello")
```

So programming is...

Programming: The process of converting instructions from high level languages to human languages.

Types of Programming languages (Execution)

Compiled

Interpreted

Both converts written code to machine language

Convert the whole code at once

Hard for error handling

Create a .exe (Executable file)
No need to recompile the code

fast

Convert code line by line

Easy for error handling
(Very specific about the error)

Need to be executed every
time you run it

Slow

Why Python

Beginner Friendly

Great community support

Third most used language
worldwide 2023

#1 language used in modern AI
development

Wide range of libraries and
framework

How to get the most out of this session?

Let's Get Started!....

IDE

Integrated Development Environment

Python IDE APP

Let's Get Started!....

```
print("hello world")
```

Python Syntax (Blocks of code)

```
# ERROR!!  
print("hello world!")  
    print("life is great")  
  
# Correct  
print("hello world")  
print("life is great")
```

```
# correct  
if x == 5:  
    print("x equals 5")  
  
# Error  
if x == 5:  
print("x equals five")
```

Multiple line print

```
print ("""  
This is  
a  
multiple line  
String  
""")
```

ASCII art

The image shows the word "welcome!" rendered in a stylized, pixelated font using only ASCII characters. The letters are constructed from various symbols like backslashes, underscores, and dots, giving it a retro, digital appearance. The exclamation mark at the end is also composed of these symbols.

Variables

Misconception: Variable is not a box that stores the data. Data is stored in the memory.
Variable just label it to be used and called
